Simulation Results

Conclusions

Starting point for a subspace representation $\Rightarrow \{x_n\}$ is arranged in a Hankel matrix:

$$\mathbf{H} = \begin{pmatrix} x_0 & x_1 & x_2 & \cdots & x_{M-1} \\ x_1 & x_2 & \ddots & \cdots & \vdots \\ x_2 & \ddots & \ddots & \cdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & x_{N-2} \\ x_{L-1} & \cdots & \cdots & x_{N-2} & x_{N-1} \end{pmatrix}$$

Standard Matrix approach

Overview

Introduction

The use of the complex exponential model

The complex exponential model

Standard Matrix approach

Decimative method

Tensor approach

Simulation Results

Conclusions

\mathbf{H} can be factorized as follows (noise-free case):

$$\mathbf{H} = \begin{pmatrix} 1 & \cdots & 1 \\ z_1^1 & \cdots & z_K^1 \\ z_1^2 & \cdots & z_K^2 \\ \vdots & \vdots & \vdots \\ z_1^{L-1} & \cdots & z_K^{L-1} \end{pmatrix} \begin{pmatrix} c_1 & & 0 \\ & \ddots & \\ 0 & & c_K \end{pmatrix} \begin{pmatrix} 1 & z_1^1 & z_1^2 & \cdots & z_1^{M-1} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ 1 & z_K^1 & z_K^2 & \cdots & z_K^{M-1} \end{pmatrix}$$

$$= \underbrace{\mathbf{SCT}^T}_{\text{rank-K matrix}} \quad (3)$$

\implies *Vandermonde decomposition*

Due to the structure of the noise-free model x_n , \mathbf{H} is rank deficient
 The rank equals the number of signal poles (model order)

Standard Matrix approach

Overview

Introduction

Introduction

Decimative method

Problem Statement

Decimation

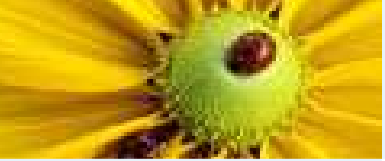

More structure

Tensor approach

Simulation Results

Conclusions

The structure of \mathbf{H} is more complex:

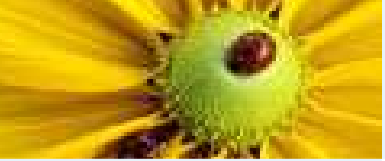

$$\mathbf{C}_d = \text{diag}\{c_1 \dots, c_k\} \cdot (\text{diag}\{z_1 \dots, z_k\})^d$$

The results could be better if this structure could be taken into account.

Is any matrix decomposition able exploit the complete structure of \mathbf{H} ?

\Rightarrow limits of the traditional linear algebra !!

The whole structure can be handled using multilinear algebra

Conclusions

Given a complex third-order tensor $\mathcal{H} \in \mathbb{C}^{L \times M \times D}$, find a rank- (K, K, K) tensor $\hat{\mathcal{H}}$ that minimizes the least-squares cost function

$$f(\hat{\mathcal{H}}) = \|\mathcal{H} - \hat{\mathcal{H}}\|^2. \quad (3)$$

Due to the n -rank constraints, $\hat{\mathcal{H}}$ can be decomposed as :

$$\hat{\mathcal{H}} = \mathcal{B} \bullet_1 \mathbf{U}^{(1)} \bullet_2 \mathbf{U}^{(2)} \bullet_3 \mathbf{U}^{(3)} \quad (4)$$

in which $\mathbf{U}^{(1)} \in \mathbb{C}^{L \times K}$, $\mathbf{U}^{(2)} \in \mathbb{C}^{M \times K}$, $\mathbf{U}^{(3)} \in \mathbb{C}^{D \times K}$ each have orthonormal columns and $\mathcal{B} \in \mathbb{C}^{K \times K \times K}$ is an all-orthogonal tensor.

Conclusions

Theorem (Unsymmetric tensor approximation) Consider a tensor $\mathcal{A} \in \mathbb{C}^{I_1 \times I_2 \times I_3}$ that is rank- (R_1, R_2, R_3) . Let the HOSVD of \mathcal{A} be given by

$$\mathcal{A} = \mathcal{B} \bullet_1 V^{(1)} \bullet_2 V^{(2)} \bullet_3 V^{(3)}.$$

Then the best rank- (R_1, R_2, \tilde{R}_3) approximation of \mathcal{A} , with $\tilde{R}_3 < R_3$, is obtained by truncation of \mathcal{B} and $U^{(3)}$.

- As a consequence of this theorem one can concentrate on the dominant part of the data tensor by decreasing the mode-3 rank without losing the data structure in the mode-1 and 2 subspace.

Conclusions

Overview

Introduction

Decimative method

Tensor approach

Simulation Results

Conclusions

- We considered oversampled signals whose poles are potentially very close,
- In the decimative matrix approach the structure is partially taken into account,
- A multilinear approach helps to reveal the rest of the structure (e.g. HOVDMD of the $(L \times M \times D)$ -tensor),
- And shows a rank deficiency: \mathcal{H} is a rank- (K, K, K) tensor,
- Ill-conditioned modes can be treated in a different manner than well-conditioned modes (unsymmetric dimensionality reduction),
- The best rank- (K, K, K') with $K' \leq K$ approximation of the noisy data tensor consistently yields a better subspace estimate than the best rank- K approximation of the noisy data matrix.
